About this page - Global Overview

What this page is for

MPG employs 4,500 people across nine cities. Voluntary attrition over the last twelve months is 13.5 % and base pay sits at 0.98 of market midpoint — a company that looks healthy in aggregate.

The executive committee has been asked to approve a **blanket 6 % salary adjustment across the LATAM hub**. The simulator below prices it. At 6 %, **\$27.8M** leaves the budget, **98 % of it lands on people already paid at or above their band minimum**, and 37 people are still below minimum afterwards. Lifting everyone to minimum costs **\$533K**.

Nothing here says which teams are the problem. That is the next page's job — asserting a conclusion before showing the rule that produced it is the habit this report is built to avoid.

The figures on this page

Headcount:
People on the books at the last month-end in view. Monthly snapshots are never summed.

Annualized Payroll USD:
Base pay only, in constant currency, so an exchange movement is never read as a pay decision.

Voluntary Attrition % LTM:
Voluntary exits over the trailing twelve months, over average headcount across the same window. Involuntary exits excluded.

Weighted Average Compa-Ratio:
Base pay against market midpoint, weighted by population — never an average of individual ratios. Blank below five people.

Company Attrition Baseline:
The company rate with every filter removed, so the reference line holds still while you filter.

vs previous period:
One month selected compares against the month before; anything wider against the year before. Each card says which.

About this page - Where the exposure is

What this page is for

Attrition costs MPG **\$83.3M** over the next twelve months if nothing changes: 599 voluntary exits, each valued at the leaver's salary times the cost of replacing them.

That cost is not spread evenly, and it does not sit where the exits sit. **Bogotá lost 148 people — two and a half times more than any other city — and ranks fourth in exposure. Dublin lost 79, barely half, and ranks first.** Exposure is exits multiplied by salary and by replacement cost, and LATAM salaries are lower. Counting heads and counting dollars point at different cities, and both readings are right for different questions.

This page sizes the problem. It does not say which teams to act on. Four of 746 cells trip a rule; the scan on the next page is where they are named and where the evidence for each one is shown.

The figures on this page

Attrition Exposure USD

Voluntary exits over the last twelve months, times average base salary, times the replacement factor. What the current rate costs over the next twelve months if nothing changes.

Replacement Factor

A declared assumption, not a measurement. 0.5× salary for Operations, 1.0× for corporate functions, 1.5× for Engineering, Data, Product and Sales, 2.0× for managers. HR literature puts the range between 0.5× and 2×; the position taken here is to state the figure and test its sensitivity, not to defend it.

Voluntary Exits LTM

Departures the employee chose. Involuntary exits and internal transfers are excluded — only the first is a retention problem.

Segments With A Rule Fired

Cells tripping at least one of the three prioritization rules. A cell tripping two counts once: the question is how many places need a conversation, not how many diagnoses were issued.

Attrition vs Baseline

A cell's attrition rate divided by the company rate. 1.00 is the company average, and the reference

About this page · The Scan

What this page is for

746 cells were scanned. 11 hold thirty people or more — below that, an attrition rate is arithmetic on too few lives to act on. 4 of those eleven trip a rule.

The point of this page is not the four. It is the seven that do not fire, and one pair in particular. Bogotá Operations IC3 and São Paulo Sales IC3 are identical: 35 people, 8 voluntary exits against 4.7 expected, 1.69× the company baseline, $p = 0.107$. Neither fires. At that population an elevated reading has close to a one-in-nine chance of being noise, and this analysis will not spend a salary budget on a one-in-nine. Under the "1.5× the baseline" rule of thumb this rule replaced, both would have been recommended for a raise.

Dublin fires on the lowest attrition on the page. 0.74× the baseline, $p = 0.854$ — statistically the quietest cell here. Rule 2 catches it through the tenure split alone: incumbents at the 25th peer percentile against recent hires at the 74th. It is the only segment found before attrition reacted, which is the only time an equity correction is cheap.

How to read the chart

Horizontal — attrition against the company baseline. 1.0 is the company rate.

Vertical — the probability of seeing this many exits, or more, if the cell ran at the company rate. Log scale, and lower is stronger: a cell near the bottom is one whose gap is hard to explain by chance. The dashed line is $\alpha = 0.05$.

Bubble size — average headcount over the trailing twelve months. Size is why the significance test matters: the same ratio on 100 people and on 35 are not the same finding.

Color — which rule fired, or pale where none did.

The figures

Attrition p-value

The one-sided Poisson probability of the observed exit count given the company rate. DAX has no Poisson function, so the exact tail is summed in logarithms against a table of $\ln(k!)$ and checked against
